

## Jackson Heights Creek EcoSummary

Jackson Heights Creek is a heavily altered stream located off Hwy 27 in northern Leon County. The stream receives runoff from the Parkhill and Greenwood Hills subdivisions, and then continues north through Lake Jackson Heights and Harbinwood subdivisions before finally entering Lake Jackson. This watershed, with residential development dating from the 1950's, displays impacts from channelized flow and aging septic tanks. Sampling was intermittent from February 2007 through October 2008, due to low flow conditions and stormwater facility construction in the channel. The stormwater facility was constructed to mitigate development impacts and to benefit both the creek and Lake Jackson.

A sinkhole opened upstream of Jackson Heights Creek in a County stormwater facility in December 2018, causing low water conditions downstream of the feature. Because of the conditions, Leon County staff only collected one water quality sample in 2019 (January 24<sup>th</sup>). The sinkhole was filled, and the repairs completed in March 2020.

As shown in **Figure 1**, transportation, utilities, urban and residential land uses make up approximately 79% of the 459-acre watershed. These types of land uses are often attributed to

increases in stormwater runoff and higher nutrient loads.

**Figure 1.** Jackson Heights Creek watershed land use.

### Background

Healthy, well-balanced stream communities may be maintained with some level of human activity, but excessive human disturbance may result in waterbody degradation.

Human stressors may include increased inputs of nutrients, sediments, and/or other contaminants from watershed runoff. Stressors can also include adverse hydrologic alterations, undesirable removal of habitat or riparian buffer vegetation, and introduction of exotic plants and animals. State water quality standards are designed to protect designated uses of the waters of the state (e.g., recreation, aquatic life, fish consumption), and exceedances of these standards are associated with interference of the designated use.

In late 2006, the U.S. Environmental Protection Agency (USEPA) set a TMDL target for Total Phosphorus of 0.15 mg/L, a 35% reduction of the previous existing concentration of 0.23 mg/L.

## Methods

Surface water samples are collected quarterly (as field conditions allow). This information is used to determine the health of Jackson Heights Creek and meets the requirements of the Florida Department of Environmental Protection (FDEP).

## Results

### *Nutrients*

The State of Florida uses Numeric Nutrient Criteria (NNC) to evaluate nutrients in waterbodies. NNC thresholds are set based on waterbody-specific characteristics and are used to determine if a waterbody meets water quality standards. The results of the four quarterly samples from a single year are used to calculate the annual geometric mean. According to FDEP requirements, the NNC threshold cannot be exceeded more than once in a three-year period. Due to low water conditions, four temporally independent samples per year could not always be collected. When viewing tables and figures, the absence of data means there was not enough data collected to fulfill data requirements.

The NNC thresholds and results are found in **Table 1**. When sampling conditions were met, NNC thresholds were never exceeded during the period of record.

As mentioned previously, the USEPA set a TMDL target for Total Phosphorus of 0.15 mg/L, a 35% reduction of the previous existing concentration of 0.23 mg/L. During the 2006-2022 sampling period, Total Phosphorus concentrations ranged from 0.036 mg/L to 0.32 mg/L (**Figure 2**), with an arithmetic mean of 0.13 mg/L. While overall phosphorus levels are still below the TMDL, the 2021 results suggest that levels appeared to be increasing and are a cause of concern. Staff concerns prompted the

inspection of the upstream Jackson Heights Creek stormwater management facilities, and the decision was made to perform major maintenance on the facilities. It is staff's belief that phosphorus levels will drop with the completion of the facilities' maintenance. While maintenance is still ongoing, Total Phosphorus values in 2022 have dropped to levels below the TMDL.

**Table 1.** NNC thresholds and sample results for Jackson Heights Creek.

Jackson Heights Creek	TN Threshold 1.03 mg/L	TP Threshold 0.18 mg/L
2009	0.38	0.09
2010	0.56	0.12
2011-2012*	-	-
2013	0.30	0.08
2014	0.32	0.09
2015*	-	-
2016	0.43	0.10
2017	0.39	0.09
2018	0.43	0.16
2019-2020*	-	-
2021	0.69	0.14
2022*	-	-

\* Due to low water conditions, staff could not collect the appropriate number of samples and thus could not determine the NNC for the noted years.

### *Fecal Coliforms and Escherichia coli (E. coli)*

Jackson Heights Creek has a history of fecal coliform levels exceeding the Class III water quality standard (400/100 mL in at least 10% of the samples). *E. coli* standards have now supplanted fecal coliform standards in Florida as an indicator of bacterial contamination. As **Figure 3** shows, *E. coli* levels exceeded the Class III water quality standard daily limit of > 410 in 10% threshold value of samples collected

over a 30-day period. Aging septic tanks, leaking sewer pipes or animal/pet waste could be contributing to the elevated *E. coli* levels in the creek.

#### *Other Parameters*

Several species of exotic plants line the bank of Jackson Heights Creek, primarily wild taro (*Colocasia* sp.). In many cases, exotic plants will crowd out and replace native plants. This may stress native wildlife, which have evolved to depend on native plants for food and shelter. The native wildlife may move away or perish if the native vegetation is replaced by exotic plants.

Other water quality parameters appear to be normal for the area and no other impairments were noted.

#### **Conclusions**

Based on ongoing sampling, Jackson Heights Creek met the NNC for the East Panhandle Region. While Total Phosphorus levels increased in 2021, levels in 2022 fell below the TMDL limit. Maintenance currently being performed on the upstream facilities probably contributed to lower phosphorus levels. *E. coli* levels exceeded

the Class III water quality standard daily limit several times over the sampling period. Aging septic tanks, leaking sewer pipes or animal/pet waste could be contributing to the elevated coliform levels. Several species of exotic plants line the bank of Jackson Heights Creek which may affect native wildlife dependent on native plants for food and shelter. Other water quality parameters appear to be normal for the area and no other impairments were noted.

Thank you for your interest in maintaining the quality of Leon County's water resources. Please feel free to contact us if you have any questions.
